### [11-C-02] Data-driven thermal control of secondary flow in a marginally turbulent square-duct flow and relevance to the invariant solutions

\*Atsushi Sekimoto<sup>1</sup>, Takashi Mitani<sup>1</sup> (1. Okayama University)

Keywords: Turbulent square-duct flow , data-driven control, optimization

2024.7.14 -19 ICCFD 12

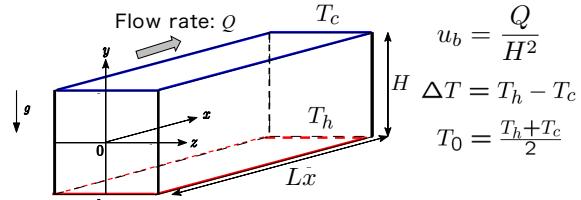

**Data-driven thermal control of secondary flow in a marginally turbulent square-duct and relevance to the invariant solutions**

○ Atsushi Sekimoto  
Okayama University  
Faculty of Environmental, Life, and Natural Science,  
Mathematical data sciences, Assoc. Prof.  
Takashi Mitani  
Okayama University, graduate school of  
Environmental, Life, and Natural Science

※ Most of computation was performed at "Wisteria" in U. of Tokyo

OKAYAMA UNIVERSITY

1

Geometry & simple heating from belowGoverning equation

$$\frac{\partial \mathbf{u}}{\partial t} + (\mathbf{u} \cdot \nabla) \mathbf{u} = -\nabla \left( \frac{p}{\rho} \right) + \frac{1}{Re_H} \nabla^2 \mathbf{u} + \boxed{\frac{Gr}{Re_H^2} T^* \mathbf{e}_y}$$

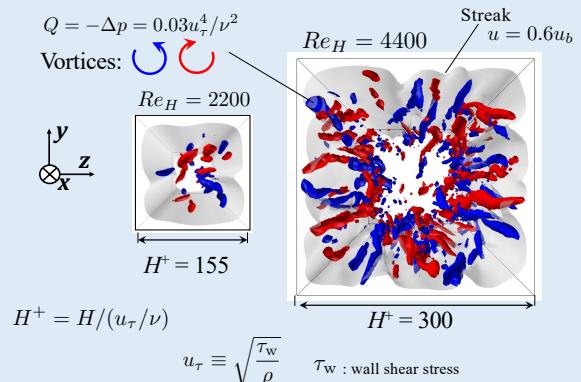

$$\frac{\partial T^*}{\partial t} + (\mathbf{u} \cdot \nabla) T^* = \frac{1}{Pr Re_H} \nabla^2 T^*$$

2

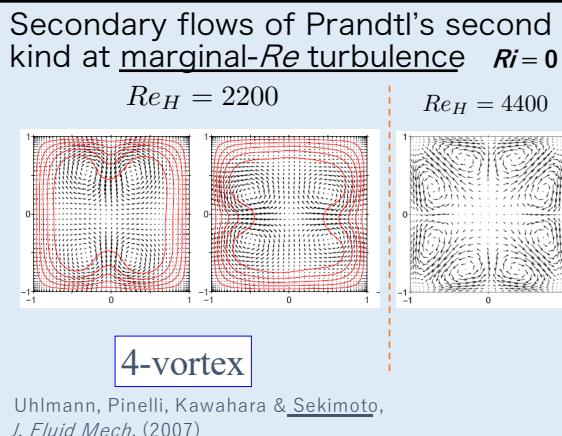

Numerical method

- Time:** pressure correction fractional-step method  
semi-implicit 3-step Runge-Kutta  
[Verzicco & Orlandi *J.Comput.Phys.*(1996)]  
 $CFL < 0.3$
- Space:** Pseudo-spectral method  
streamwise( $x$ ), Fourier expansions  
cross-streamwise( $y, z$ ), Chebyshev polynomials  
 $\Delta x^+ < 16.4$     $\Delta y^+, \Delta z^+ < 5.4$
- 2D Helmholtz equations:**  
Chebyshev collocation (fast diagonalization  
technique) [Haldenwang, *J. Comput. Phys.* (1984)]  
⇒ "dgemm"×4 → GPU acceleration for high-Re  
but low-Re in my talk, today

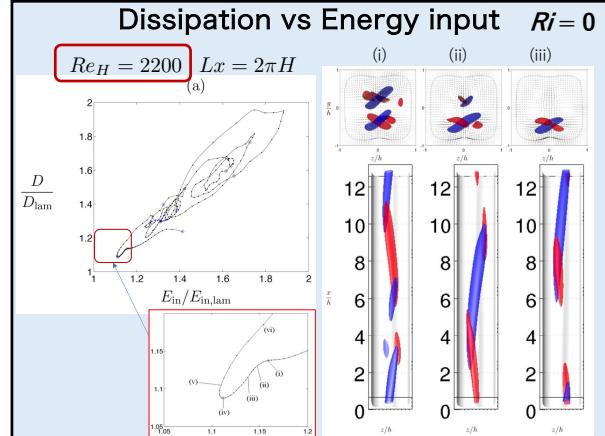

3

Coherent Structures in a minimal box

4

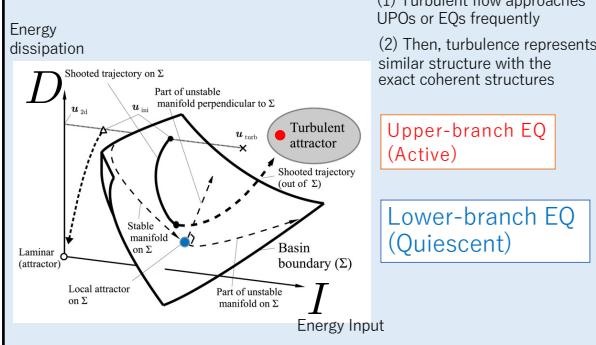

5

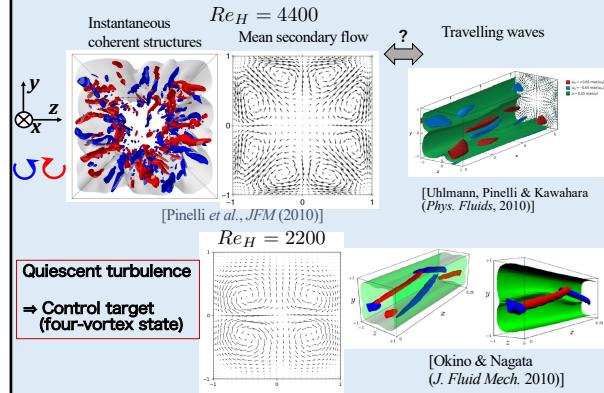

6

## Shooting dynamics in phase space

7

## Secondary flow of Prandtl's second kind

8

### Velocity scales

$$\begin{aligned} 1. \text{ mean bulk velocity: } u_b \\ 2. \text{ friction velocity: } u_\tau = \sqrt{\tau_w / \rho} \\ 3. \text{ buoyancy-induced velocity: } u_g = \sqrt{|g| \beta \Delta TH} \end{aligned}$$

Friction coefficient

$$f = 8 \left( \frac{u_\tau}{u_b} \right)^2$$

### Non-dimensional parameters:

$$\begin{aligned} Re_H &\equiv \frac{u_b H}{\nu}, \\ Pr &\equiv \frac{\nu}{\kappa} \\ Ri &\equiv \frac{|g| \beta \Delta TH}{u_b^2} = \frac{Gr}{Re_H^2} = \left( \frac{u_g}{u_b} \right)^2 \end{aligned}$$

9

## Previous my works

### • Reynolds-number effect

[Uhlmann et al., *JFM* (2007)]

- 4-vortex state in a iso-thermal square duct

 $Re_H = 2200 \sim 3000$ 

- Puffs in a square duct as in a pipe flow

 $Re_H = 1800 \sim 2000$ 

### • Richardson-number effect

[Pinelli et al., *JFM* (2010)]

- Turbulence-driven vs buoyancy-driven

 $Pr = 0.7$ [Sekimoto, Kawahara, Sekiyama et al. *PoF* (2011)]

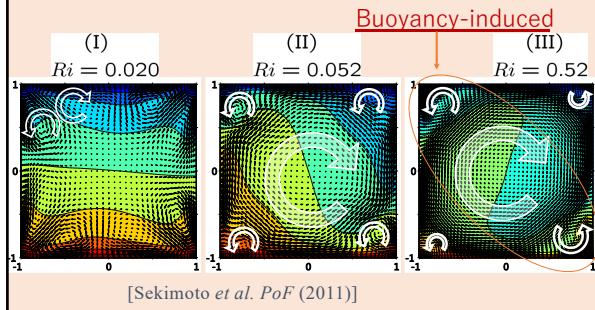

- (Prandtl number effect)

10

## Mean temperature & secondary flow

$$\begin{aligned} Lx &= 2\pi H \\ Re_H &= 4400 \end{aligned}$$

- Buoyancy effects appear at:  $Ri \sim 0.025$
- Buoyancy is dominant at:  $Ri > 0.25$

11

## Coherent Structures

$$Re_H = 4400$$

$$u = 0.6u_b \quad Q = -\Delta p = 0.03u_\tau^4/\nu^2$$

(I)  
 $Ri = 0.00026$

(II)  
 $Ri = 0.052$

(III)  
 $Ri = 0.52$

[Sekimoto et al. *PoF* (2011)]

12

### Stabilization of a 4-vortex state $Pr = 0.7$ by heating from below $Lx = 20\pi H$

	$Ri = 0$	$Ri = 0.01$	$Ri = 0.1$
$Re_H = 2200$	Turb.	Turb.	4-vortex
$Re_H = 2000$	Puff	Puff	4-vortex
$Re_H = 1800$	Puff	Puff	4-vortex
$Re_H = 1600$	Laminar	Laminar	Laminar

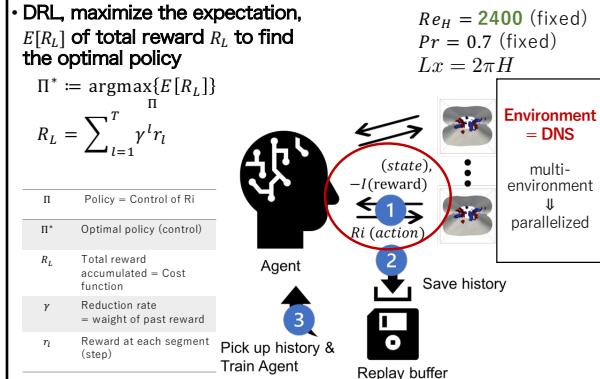

- Buoyancy stabilises a 4-vortex-type secondary flow at moderate Richardson numbers, suggesting a control strategy by using buoyancy force

- Automatic complex control  
→ deep reinforcement learning

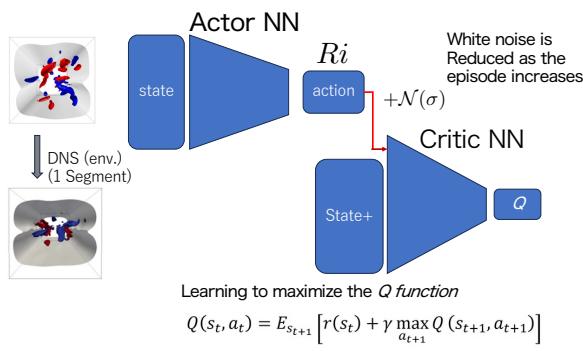

13

### Deep Reinforcement Learning

14

### Framework of DDPC algorithm

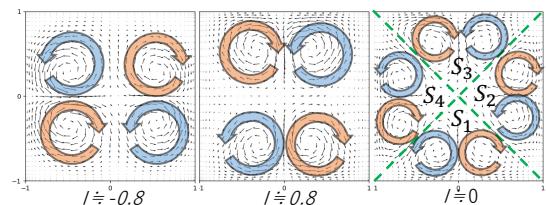

15

### Reward: four-vortex state indicator, $I$

- The indicator function using the mean streamwise vorticity [Uhlmann et al.(2007)]

$$I(t) \equiv \frac{S_1 + S_3 - S_2 - S_4}{S_1 + S_3 + S_2 + S_4}, \quad S_i = \iint_{\Omega_i} (\omega_x)_x^2 dy dz$$

$$\Omega_1: \{(y, z) | y < z \cap y < -z\}, \Omega_2: \{(y, z) | y < z \cap y > -z\}, \\ \Omega_3: \{(y, z) | y > z \cap y > -z\}, \Omega_4: \{(y, z) | y > z \cap y < -z\}$$

16

### Cost function in RL

- $Re_H = 2400$ ,  $Pr = 0.7$  (fixed), control the heat input  $Ri = 0.0 - 0.1$  (limited range) observing environment (DNS)

17

### Details of RL

- Algorithm
  - DDPG [Lillicrap et al.(2016)]
- Two DNNs: ADAM optimizer
- State [= what we observe from m env. (DNS)]
  - The Fourier modes of cross-sectional velocities,  $v, w$   $[0, 1, 2]$   
→ Focusing on Large-scale motion
- Action (control)  $Ri = [0 \sim 0.1]$
- $Re_H = 2400$  (fixed)  
 $Pr = 0.7$  (fixed)  
 $Lx = 2\pi H = 4\pi h$
- Reward [from env. (DNS)]
  - based on the indicator function
    - If  $I > 0.5$ : Reward,  $r = 0$
    - Else: Reward,  $r = -I$
- Episode (=1 run of DNS)
  - 1 episode ≈ 5400  $h/u_b$
  - Divide each episode into 200 segments
  - The different initial condition for each episode (30 episode)
- Segment (the interval of control)
  - 1 segment =  $27 \frac{h}{u_b}$   
→ no history correlations between previous control ( $\sim 2$  washout time) → "Markovian"

18

## The structure of Neural Networks 🤖

- DDPG has two NN: Actor NN calculates the action from the state, and the Critic NN does Q of actions for each state
- Actor NN
  - state(13068)  $\Rightarrow$  (32768)  $\Rightarrow$  (4096)  $\Rightarrow$  (512)  $\Rightarrow$  (64)  $\Rightarrow$  action
- Critic NN
  - state+, action(13069)  $\Rightarrow$  (32768)  $\Rightarrow$  (4096)  $\Rightarrow$  (512)  $\Rightarrow$  (64)  $\Rightarrow$  Q-value
- Activation function: ReLU
- Fully-connected

## Hyper parameter for NNs

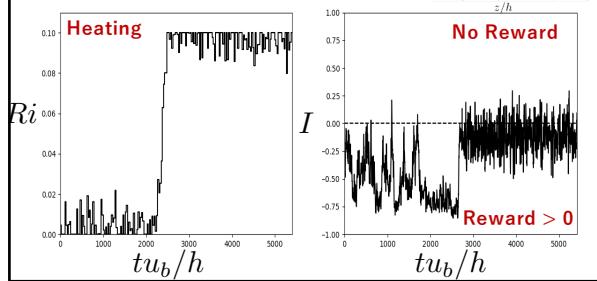

- Learning rate
  - Actor\_Lr = 0.0001
  - Critic\_Lr = 0.001
- Reduction rate (almost no consideration from past rewards)
  - 0.99
- soft update parameter (target NN)
  - 0.005
- Replay buffer
  - common for all episodes and agents, necessary for parallel environments
    - 2000 buffer (remember the latest 10 episodes)
    - Batch size: 64

19

20

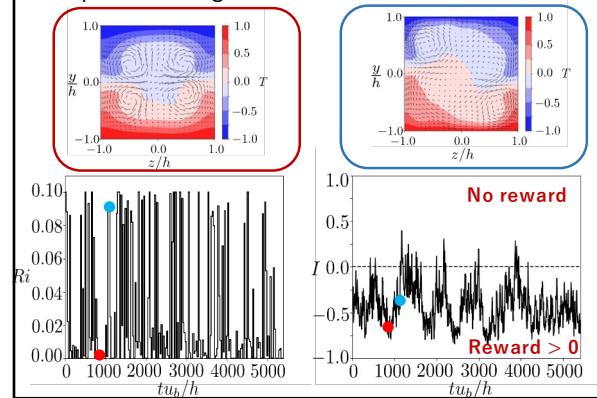

## Result: episode 1

- Increases  $Ri = 0.1$ 
  - The thermally-driven circulation  $\Rightarrow$  failed

21

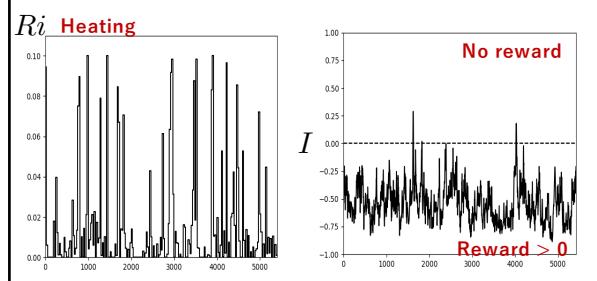

## Episode 3, agent becomes smarter

22

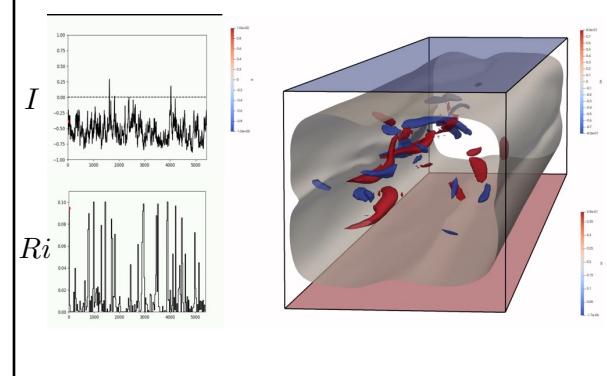

## Episode 8

- Switching between  $Ri = 0$  and  $Ri = 0.1$ 
  - An intermittent heat control is realized
  - It keeps one on the secondary flow pattern of  $I < 0$

23

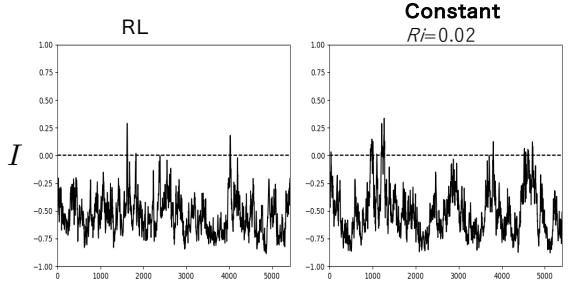

## Control: ON (Movie)

24

Constant heating ( $Ri=0.02$ ) vs RL-control [from the same initial condition]

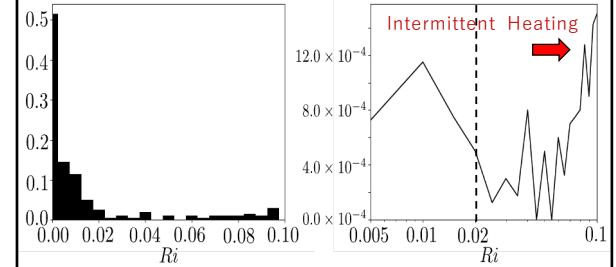

- Dynamic heating controlled by RL achieves more-stable four-vortex pattern...

25

### Contribution of intermittent heating

- $Ri \rightarrow$  probability density function (PDF, left) → pre-multiplied  $Ri$ , PDF is multiplied by  $Ri$  (right)
- In logarithmic scale in  $Ri \rightarrow$  Area corresponds to the total heat input
- Compare to the constant heating ( $Ri = 0.02$ ) → 20% heat reduction

26

### Summary and perspectives

- Complex 3-D flow with Re-, Ri-, Pe numbers
  - (also aspect ratios, As, Computational domain, Lx, etc.)
  - Stabilized the mean secondary flow pattern, which is called as a corner flow, using buoyancy force → heat enhancement, particle migrations (or separations), control in a micro-reaction channel
- Difficulties of flow control from the strong nonlinearity of turbulence
  - Successful nonlinear control method using (deep) reinforce mentlearning
    - now, targeting a specific known flow pattern (4-vortex state)
    - Background physics is important for the further application with ML techniques
      - AI technology
      - The target flow is realizable? Dynamical system approach of turbulence
      - Which ML models are suitable? How do we reduce the complexity → GPU mem.
      - How about hig-Re?
- High-fidelity CFD are expensive
  - Parameter optimization using Bayes optimization or GA algorithm
  - Keep developing the advanced GPU-accelerated code (or QPU-acceleraged?)
  - Scale up
    - Power-game in industry and international-collaboration in academic

27

Thank you very much
